# **Analog Multiplexers/Demultiplexers**

The MC14051B, MC14052B, and MC14053B analog multiplexers are digitally–controlled analog switches. The MC14051B effectively implements an SP8T solid state switch, the MC14052B a DP4T, and the MC14053B a Triple SPDT. All three devices feature low ON impedance and very low OFF leakage current. Control of analog signals up to the complete supply voltage range can be achieved.

- Triple Diode Protection on Control Inputs
- · Switch Function is Break Before Make
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Analog Voltage Range (VDD VEE) = 3.0 to 18 V
   Note: VEE must be ≤ VSS
- · Linearized Transfer Characteristics
- Low-noise 12 nV/√Cycle, f ≥ 1.0 kHz Typical
- Pin-for-Pin Replacement for CD4051, CD4052, and CD4053
- For 4PDT Switch, See MC14551B
- For Lower R<sub>ON</sub>, Use the HC4051, HC4052, or HC4053 High–Speed CMOS Devices

<sup>#</sup>Data labeled "Typ" is not to be used for design purposes, but is intended as an indication of the IC's potential performance.

<sup>\*</sup> For voltage drops across the switch ( $\Delta V_{switch}$ ) > 600 mV ( > 300 mV at high temperature), excessive  $V_{DD}$  current may be drawn, i.e. the current out of the switch may contain both  $V_{DD}$  and switch input components. The reliability of the device will be unaffected unless the Maximum Ratings are exceeded. (See first page of this data sheet.)

<sup>\*</sup> The formulas given are for the typical characteristics only at 25°C.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation,  $V_{in}$  and  $V_{out}$  should be constrained to the range  $V_{SS} \le (V_{in} \text{ or } V_{out}) \le V_{DD}$ . Unused inputs must always be tied to an appropriate logic voltage level (e.g., either  $V_{SS}$ ,  $V_{EE}$ , or  $V_{DD}$ ). Unused outputs

must be left open.

<sup>#</sup>Data labelled "Typ" is not lo be used for design purposes but In intended as an indication of the IC's potential performance.

# **APPLICATIONS INFORMATION**

Figure A illustrates use of the on–chip level converter detailed in Figures 2, 3, and 4. The 0–to–5 V Digital Control signal is used to directly control a 9  $V_{p-p}$  analog signal.

The digital control logic levels are determined by  $V_{DD}$  and  $V_{SS}$ . The  $V_{DD}$  voltage is the logic high voltage; the  $V_{SS}$  voltage is logic low. For the example,  $V_{DD} = +5$  V = logic high at the control inputs;  $V_{SS} = GND = 0$  V = logic low.

The maximum analog signal level is determined by  $V_{DD}$  and  $V_{EE}$ . The  $V_{DD}$  voltage determines the maximum recommended peak above  $V_{SS}$ . The  $V_{EE}$  voltage determines the maximum swing below  $V_{SS}$ . For the example,  $V_{DD} - V_{SS} = 5$  V maximum swing above  $V_{SS}$ ;  $V_{SS} - V_{EE} = 5$  V maximum swing below  $V_{SS}$ . The example shows a  $\pm$  4.5 V signal which allows a 1/2 volt margin at each peak. If voltage transients

above  $V_{\mbox{DD}}$  and/or below  $V_{\mbox{EE}}$  are anticipated on the analog channels, external diodes (Dx) are recommended as shown in Figure B. These diodes should be small signal types able to absorb the maximum anticipated current surges during clipping.

The absolute maximum potential difference between  $V_{DD}$  and  $V_{EE}$  is 18.0 V. Most parameters are specified up to 15 V which is the *recommended* maximum difference between  $V_{DD}$  and  $V_{EE}$ .

Balanced supplies are not required. However, VSS must be greater than or equal to  $V_{EE}$ . For example,  $V_{DD} = +10 \text{ V}$ ,  $V_{SS} = +5 \text{ V}$ , and  $V_{EE} - 3 \text{ V}$  is acceptable. See the Table below.
